

# Converting Repeating Decimals to Fractions

## The "Multiply by 10<sup>n</sup>, Stack - Subtract - Solve - Simplify" Method

Find more helpful math resources at the Learning Center Math Tutorials page: <http://www.lsc.edu/learningcenter/math.asp>

**Step 1:** Let  $x$  equal the repeating decimal number. This step creates an equation,  $x = \text{original decimal number}$ .

### Example 1

$$x = 0.55555 \dots$$

### Example 2

$$x = -1.04242424242 \dots$$

**Step 2:** Identify the repeating digit(s) in the decimal number.

The repeating digit is 5.

The repeating digits are 42.

**Step 3:** Multiply this equation by a **power of 10** to move the repeating digits to the **LEFT** of the decimal point. This step creates a second equation,  $10^n = 2^{\text{nd}} \text{ decimal number}$ .

To move one decimal place, multiply by  $10^1$  (10).

$$10x = 5.55555 \dots$$

To move three decimal places, multiply by  $10^3$  (1000).

$$1000x = -1042.4242424242 \dots$$

**Step 4:** Look at the original decimal number (from step 1). If the repeating digits aren't already immediately to the **RIGHT** of the decimal point, multiply the second equation by another power of 10 to achieve this. This step creates a third equation,  $10^{n+?} = 3^{\text{rd}} \text{ decimal number}$ .

The repeating digit in the step 1 equation is already to the right:  $x = 0.55555 \dots$

A zero is immediately to the right of the decimal point:

$$x = -1.04242424242 \dots$$

So, multiply by  $10^1$  (10).

$$10x = -10.4242424242 \dots$$

**Step 5:** **Stack** the 2<sup>nd</sup> and 1<sup>st</sup>—or 2<sup>nd</sup> and 3<sup>rd</sup>—equations (make sure to **align the decimal points**), and then **Subtract** the left sides of each and the right sides of each. The resulting difference is a new equation. **Subtraction eliminates the repeating digits!**

$$\begin{array}{r} 10x = 5.55555 \dots \\ - x = 0.55555 \dots \\ \hline 9x = 5 \end{array}$$

$$\begin{array}{r} 1000x = -1042.4242424242 \dots \\ - 10x = -(-10.4242424242 \dots) \\ \hline 990x = -1032 \end{array}$$

*Subtraction changes the sign of  $-10.4242 \dots$  to positive.*

**Step 6:** Solve the new equation for  $x$ . The result will be a **fraction** (or ratio of integers)  $\dots$  but you're not quite done.

*Divide each side by 9 to isolate  $x$ .*

$$\begin{array}{r} 9x = 5 \\ 9 \quad 9 \\ \hline x = 5/9 \end{array}$$

$$\begin{array}{r} 990x = -1032 \\ 990 \quad 990 \\ \hline x = -1032/990 \end{array}$$

*Divide each side by 990 to isolate  $x$ .*

**Step 7:** Simply the fraction if it's not already in lowest terms. Now you're done!

5/9 is already in lowest terms.

$$0.55555 \dots = 5/9$$

$$-1032/990 = -516/495$$

$$-1.424242 \dots = -516/495$$

*Both the numerator and denominator are divisible by 2.*

# Another Way to Convert Repeating Decimals to Fractions

## The "Break-Down" & "Re-Build" Method

This method may be useful when the repeating digits start several decimal places behind the decimal point.

**Step 1: Break down** the repeating decimal by expressing it as a **sum** of fractions, with the repeating portion at the end (use place values to figure this out). **You do this in order to isolate the repeating part.**

### Example

$$1.873535 \dots = 1/1 + 87/100 + 0.003535 \dots \quad \text{Note that the whole number } 1 = 1/1$$

**Step 2:** Focus only on the repeating portion of the sum (ignore the rest). **Let x = the repeating portion.** Multiply this equation by a **power of 10** to move the repeating digits immediately to the **LEFT** of the decimal point (in other words, to eliminate any zeros preceding the repeating digits).

$$x = 0.003535 \dots$$

$$100x = 0.353535 \dots$$

**Step 3:** Express this new repeating decimal number as a **sum** in order to **isolate the repeating part** (refer to step 1).

$$100x = 35/100 + 0.003535 \dots$$

**Step 4:** Recall that  $x = 0.003535 \dots$ , so you can replace this part with  $x$  in the equation above.

$$100x = 35/100 + x$$

**Step 5:** Solve for  $x$ . This step should yield the repeating portion expressed as a fraction.

$$\begin{array}{r} 100x = 35/100 + x \\ -x \qquad \qquad -x \\ \hline 99x = 35/100 \end{array}$$

*Divide each side by 99 (or multiply by 1/99).*

$$99x * 1/99 = 35/100 * 1/99$$

*Now 0.003535... is a fraction!*

$$x = 35/9900$$

**Step 6:** In the sum from step 1, replace the repeating decimal portion with its fractional equivalent.

$$1.873535 \dots = 1/1 + 87/100 + 35/9900$$

**Step 7:** Now that each element of the sum is a fraction, it's time to **re-build** by adding the fractions together. Make sure to use a common denominator. Reduce if needed.

$$1.873535 \dots = 9900/9900 + 8613/9900 + 35/9900 = 18548/9900 = 4637/2475$$

*Both the numerator and denominator are divisible by 4.*

$$1.873535 \dots = 4637/2475$$
